FLUCTUATION INEQUALITIES WITH APPLICATIONS TO CONVERGENCE AND REGULARTTY OF STOCHASTIC PROCESSES INDEXED BY $[0,1]^{q}$.<br>Antoni Sintes Blanc Universitat Autonoma de Barcelona Spain

#### Abstract

Extending results of Billingsley and Chentsov, Bickel \& Wichura proved some fluctuation inequalities for processes with multi-dimensional time parameter. In the same order of ideas we give here an extension to the case that the marginals of the control measure are not necessarily continuous,

Applications of this results to get some useful convergen ce criteria for $[0,1]^{G}$ indexed processes are given, as well as a theorem on regularity of right stochastically continuous proce sses.

AMS subject classification (1.983). 60F05, 60G05
Key words and phrases: Fluctuation inequalities, weak convergen ce, $D[0,1]^{\sigma}$-valued random variables, regularity.

0 . Introduction.

In (1) P. Bickel \& M. Wichura prove fluctuation inequali ties for processes indexed by a q-dimensional parameter set, extending results of Chentsov and Billingsley, (2), (3). Here we extend their theorem 3 to the case where the marginals of $m$ are not necessarily continuous. Bickel \& Wichura (op. cit. pg. 1665, final) announce a possible extension to the case that $m$ depends on $n$, and the measures $m_{n}$ converge weakly to a measure with continuous marginals. Our extension has a different character: $m$ will be fixed (independent of $n$ ), we will suppose instead that processes in question have independent increments, and the constants that appear in their theorem 1 will depend on $m, q, \gamma$ and $\beta$, in our case. This is the content of point 2. Point 3 is devoted to give applications of the fluctuation inequalities to the convergence of processes indexed by $[0,1]^{q}$. At point 4 we see an application to the regularity of processes with independent increments over $[0,1]^{\text {q. }}$. On this later result it is worthy to say that R . Morkvenas $\{6\rangle$, using Dynkin-Kinney's type conditions, proves that all processes with independent increments and stochastically continuous have versions in $D[0,1]^{q}$. Our Thm. (4.1) is not enclosed in his result because we only impose right stochastic continuity.

1. Definitions and previous results. Notation is much as in (1). Let $q$ be a positive integer and $T_{1}, T_{2}, \ldots, T_{q}$
subsets of $[0,1]$ each of which contains 0 and 1 , and is finite or $[0,1]$. Let $\left\{X_{t}\right\}_{t \in T}$ be a stochastic process indexed by $T=T_{1} \times T_{2} \times \ldots \times T_{q}$ with values in a normed space ( $\mathrm{E}, \mathrm{I} . \mathrm{I}$ ). We suppose X is separable and vanish on the lower boundary of $T, \partial_{i n f} T, i, e$, the points of $T$ having some coordinate equal to 0 .

For each $p, 1 \leqslant p \leqslant q$, and each $t \in T_{p}$ we define

$$
\begin{array}{r}
x_{t}^{(p)}: T_{1} x \ldots x \hat{T}_{p} x \ldots x T_{q} \longrightarrow E \quad b y \\
x_{t}^{(p)}\left(t_{1}, \ldots, t_{p-1}, t_{p+1}, \ldots t_{q}\right)=x\left(t_{1}, \ldots, t_{p-1}, t^{\prime}, t_{p+1}, \ldots, t_{q}\right) .
\end{array}
$$

If $s \leqslant t \leqslant u$ in $T_{P}$, we define

$$
m_{p}(s, t, u)(x)=\min \left(\left\|X_{t}^{(p)}-X_{s}^{(p)}\right\|,\left\|X_{u}^{(p)}-X_{t}^{(p)}\right\|\right)
$$

Where || . Il is the supremum norm.

Definition (1.1):

$$
\begin{gathered}
M_{p}^{\prime \prime}(X)=\sup \left\{m_{p}(s, t, u)(X): s \leqslant t \leqslant u ; s, t, u \in T_{p}\right\} \\
M^{\prime \prime}(X)=\max _{1 \leqslant p \leqslant q} M_{p}^{\prime \prime}(X) \\
M(X)=\sup \{|X(t)|: t \in T\} \square
\end{gathered}
$$

The following proposition is very useful and quite delementary.

Proposition $(1.2):$ If $1_{q}=(1, \ldots, 1)$, then

$$
\begin{aligned}
& M(X) \leqslant \sum_{p=1}^{q} M_{p}^{\prime \prime}(X)+\left|X\left(1_{q}\right)\right| \leqslant \\
& \leqslant q \cdot M^{\prime \prime}(X)+\left|X\left(1_{q}\right)\right| \square
\end{aligned}
$$

We say that $B \subset T$ is a block if

$$
B=\prod_{p=1}^{q}\left(s_{p}, t_{p}\right]
$$

we also write $B=(s, t]$ where $s=\left(s_{1}, \ldots, s_{q}\right)$ and $t=\left(t_{1}, \ldots, t_{q}\right)$.

Denote $X(B)$ the rectangular increment of $X$ over the block B, i.e.:

$$
x(B)=\epsilon_{1}^{1} \sum_{=0}^{1} \sum_{2}^{1}=0 \epsilon_{q}^{\sum_{q}}=0(-1)^{q-\sum_{p=1}^{q} \epsilon_{p}} x\left(s_{1}+\epsilon_{1}\left(t_{1}-s_{1}\right), \ldots, s_{q}+\epsilon_{q}\left(t_{q}-s_{q}\right)\right)
$$

We say that $X$ has independent increments if $X(B)$ and $X(C)$ are independent random variables whenever $B$ and $C$ are disjoint blocks.

Definition (1.3): We write $X \in C_{i}^{m}(\beta, \gamma)$ if $X$ has independent increments and

$$
\mathrm{P}\{|\mathrm{X}(\mathrm{~B})| \geqslant \lambda\} \leqslant \lambda^{\boldsymbol{- \gamma}}(\mathrm{m}(\mathrm{~B}))^{\beta}, \forall \lambda>0
$$

for all $B \subset T$, block of $T$, where $\gamma$ and $\beta$ are fixed positive reals, and $m$ is a finite measure over $T$ vanishing over ${ }_{\text {inf }} T$

Evidently if $X \in C_{i}^{m}(\beta, \gamma)$ then the pair $(X, m)$ belongs to $C(2 \beta, 2 \gamma)$ in the sense of Bicker \& Wichura (1).

Theorem (1.4): If (X,m) $\mathcal{C}(\beta, \gamma)$, ice. if for all pair of disjoint blocks $B, C$ of $T$ we have

$$
p\{|X(B)| \geqslant \lambda, \quad|X(C)| \geqslant \lambda\} \leqslant \lambda^{-\gamma}(m(B \cup C))^{\beta}, \forall \lambda>0
$$

then $\forall \lambda>0$

$$
P\left\{M_{p}^{\prime \prime}(X) \geqslant \lambda\right\} \leqslant K_{q}(\beta, \gamma\rangle \cdot \lambda^{-\gamma}(m(T))^{\beta}
$$

for all $p, \quad l \leqslant p \leqslant q, \quad$ and

$$
P\left\{M^{\prime \prime}(X) \geqslant \lambda\right\} \leqslant L_{q}(\beta, \gamma) \lambda^{-\gamma}(m(T))^{\beta}
$$

This is theorem 1 of Bickel and Wichura(1).

Introduction of the following moduli is suggested by the identification

$$
D_{q}=D\left([0,1]^{q} ; R\right)=D\left([0,1] ; D_{q-1}\right) .
$$

Definition (1.5): If $x \in D_{q}$ and $\delta>0$ we define

$$
\begin{aligned}
w_{x}^{\prime \prime \prime}(p)(\delta)= & \sup ^{s, t, u \in T_{p}} \min \left(\left\|x_{t}^{(p)}-x_{s}^{(p)}\right\|,\left\|x_{u}^{(p)}-x_{t}^{(p)}\right\|\right) \\
& s \leqslant t \leqslant u, u-s \leqslant \delta \\
& w_{x}^{\prime \prime}(\delta)=\max \quad 1 \leqslant p \leqslant q
\end{aligned}
$$

In what follows we shall also need the following result on tightness in the space $\left(\mathrm{D}(0,1)^{q} ; D_{\mathrm{q}}\right)$, whose proof may be found in Neuhaus (7).

Theorem (1.6): A sequence $\left\{P_{n}\right\}_{n=1}^{\infty}$ of probability measures on (D[0,1] $\left.{ }^{q}, D_{q}\right)$ is tight if and only if:
i) For all $\eta>0$, there exists $a \in \mathbb{R}$ such that
$P_{n}\left\{x: \sup _{t}|x(t)|>a\right\} \leqslant \eta, \quad$ for all $n \geq 1$.
ii) For all $\varepsilon>0$, $\eta>0$, there exist $\delta, 0<\delta<1$, and $n_{0}$, such that for $n \geqslant n_{0}$

$$
P_{n}\left\{x: w_{x}^{1}(\delta) \geqslant \epsilon\right\} \leqslant \eta
$$

## 2. Fluctuation inequalities

Theorem (2.1): There exists a constant $K$, $K=K(q, \beta, \gamma, m(T))$, such that for all process $X \in C_{i}^{m}(\beta, \gamma)$,
(see Def. (1.3)), is

$$
P\left\{M_{p}^{\prime \prime}(X) \geqslant \lambda\right\} \leqslant K\left(\lambda^{-4 \gamma} v \lambda^{-2 \gamma}\right) \quad\left(m_{p}[0,1]\right)^{2 \beta}\left(1-\frac{J_{p}[0,1]}{m_{p}[0,1]}\right)^{\beta}
$$

for all $p, 1 \leqslant p \leqslant q$, where $J_{p}[0,1]$ is the maximum jump of the distribution function $F_{m_{p}}$ of the $p$-th marginal, $m_{p}$, of $m$, and $v$ means "the greatest of".

## Proof:

Step 1. $q=1$ and $T$ finite. Let $0=t_{0}<t_{1}<\ldots<t_{m}=1$ be the points of $T$. Define the process

$$
\left.Y(u)=\sum_{i=0}^{m-1} X\left(t_{i}\right) I_{\left[t_{i}, t_{i+1}\right.}\right)^{(u)}+X\left(t_{m}\right) I_{\left\{t_{m}\right\}}(u)
$$

over $[0,1]$. Then, if

$$
\begin{aligned}
& t_{i-1} \leqslant s<t_{1} \leqslant t_{h} \leqslant t<t_{h+1} \leqslant t_{k} \leqslant u<t_{k+1} \\
& P\{m(s, t, u)\{y) \geqslant \lambda\} \leqslant \lambda^{-2 \gamma}\left(\sum_{j=i}^{h} m\left\{t_{j}\right\}\right)^{\beta}\left(\sum_{j^{\prime}=h+1}^{k} m\left\{t_{j},\right\}\right)^{\beta}= \\
& =\lambda^{-2 \gamma}\left(\sum_{j=i, j,=h+1}^{h} m\left\{t_{j}\right\} m\left\{t_{j},\right\}\right)^{\beta} \leqslant \\
& \leqslant \lambda^{-2 \gamma}\left[\left(\sum_{j=i}^{k} m\left\{t_{j}\right\}\left(\sum_{j=h+1}^{k} m\left\{t_{j}, b\right)^{\beta} \wedge\left(\sum_{j=i}^{k} m\left\{t_{j}\right)\left(\sum_{j=1}^{h} m\left(t_{j}\right\}\right)\right)^{\beta}\right] \leqslant\right.\right. \\
& \leqslant \lambda^{-2 \gamma}\left[\left(m(T)-J_{m}(T)\right) \sum_{j=i}^{k} m\left\{t_{j}\right\}\right]^{\beta} \leqslant \\
& \leqslant \lambda^{-2 \gamma}\left(m(T)-J_{m}(T)\right)^{\beta}\left(\sum_{j=i}^{k-1} 2 m\left\{t_{j}\right\}+m\left\{t_{k}\right\}-m\left\{t_{i}\right\}\right\}^{\beta}=
\end{aligned}
$$

$$
\begin{gathered}
=\lambda^{-2 \gamma}\left(m(T)-J_{m}(T)\right)^{\beta}\left(\sum_{j=1}^{k-1} 2 m\left\{t_{j}\right\}+m\left\{t_{k}\right\}-\sum_{j=1}^{i-1} 2 m\left\{t_{j}\right\}-m\left\{t_{i}\right\}\right)^{\beta}= \\
=\lambda^{-2 \gamma}\left(m(T)-J_{m}(T)\right)^{\beta}\left(F\left(t_{k}\right)-F\left(t_{i}\right)\right)^{\beta} \leqslant \\
\leqslant \lambda^{-2 \gamma}\left(m(T)-J_{m}(T)\right)^{\beta}(F(u)-F(s))^{\beta}
\end{gathered}
$$

where $F$, continuous, is defined by the relations $F(0)=0, F\left(t_{j}\right)-F\left(t_{j-1}\right)=m\left\{t_{j}\right\}+m\left\{t_{j-1}\right\}$ and is linear over the intervals $\left[t_{j-1}, t_{j}\right]$.

Hence, the proces $Y$, together with the measure, m', associated to the distribution function $F^{\prime}=\left(m(T)-J_{m}(T)\right) F$, belongs to $C(\beta, 2 \gamma)$. By theorem (1.4) we have

$$
\begin{aligned}
& P\left\{M_{1}^{\prime \prime}(X) \geqslant \lambda\right\}=P\left\{M_{1}^{\prime \prime}(Y) \geqslant \lambda\right\} \leqslant K \lambda^{-2 \gamma}\left(m^{*}(T)^{\prime}\right)^{\beta}= \\
& =K \lambda^{-2 \gamma}\left(m(T)-J_{m}(T)\right)^{\beta}(F(1))^{\beta} \leqslant \\
& \leqslant 2^{\beta} K \lambda^{-2 \gamma}(m(T))^{\beta}\left(m(T)-J_{m}(T)\right)^{\beta}
\end{aligned}
$$

where we have used $F(1) \leqslant 2 m(T)$. This proves the theorem in this case.

Step 2. $G=1, T=[0,1], m$ arbitrary. Let $0=t_{0}<t_{1}<\ldots<t_{m}=1$, and $y$ the process $x$ restricted to $\left\{t_{0}, \ldots, t_{m}\right\}$.

Define $v$ as in step 4 , proof of theorem 1 , in

Bickel \& Wichura (1):

$$
\begin{gathered}
v\left\{t_{j}\right\}=m\left(t_{j-1}, t_{j}\right\} \text { if } j \geqslant 1 \\
v\left(t_{o}\right)=0
\end{gathered}
$$

Then $y \in C_{i}^{U}(\beta, \gamma)$, as a process over $\left\{t_{0}, t_{1}, \ldots t_{m}\right\}$.
Step 1 now implies

$$
\begin{gathered}
P_{\left\{M_{1}^{\prime \prime}(Y) \geqslant \lambda\right) \leqslant \lambda^{-2 \gamma} K\left(v\left\{t_{0}, t_{1}, \ldots, t_{m}\right\}\right)^{2 \beta}\left(1-\frac{J_{v}\left\{t_{0}, t_{1}, \ldots, t_{m}\right\}}{v\left\{t_{0}, \ldots, t_{m}\right\}}\right)^{\beta}=}=K \lambda^{\left.-2 \gamma_{(m(T)}\right)^{2 \beta}\left(1-\frac{J_{v}(0,1]}{m(0,1]}\right)^{\beta} .} .
\end{gathered}
$$

If now we take limit when $m \rightarrow \infty$, the set $\left\{t_{0}, t_{1}, \ldots, t_{m}\right\}$ increasing to a dense subset of $[0,1]$ that contains the points of discontinuity of $F$, we obtain (by separability):

$$
P\left\{M_{1}^{\prime \prime}(Y) \geqslant \lambda\right\} \leqslant K \lambda^{-2 \gamma}(m(T))^{2 \beta}\left\{1-\frac{J_{m}[0,1]}{m(T)}\right\}^{\beta} .
$$

Step 3) $g \geq 2, T$ and $m$ arbitrary. We know that the theorem is true for $q=1$. We now will show our result to be true for $p=1$; for other $p$ the argument is the same.

Like in step 5 of Bickel \& Wichura's proof of theorem 1, the key point is that the version for $q=1$ of our theo rem works for the function valued proces $\left\{X_{t}^{(1)}\right\} t \in T_{1}$. To
show this it is enough to find bounds of its increments.

## Remember that

$$
m_{p}(s, t, u)(x)=\min \left(\left\|X_{t}^{(p)}-x_{s}^{(p)}\right\|,\left\|X_{u}^{(p)}-x_{t}^{(p)}\right\|\right) .
$$

Let $T^{*}=T_{2} \times \ldots \mathrm{T}_{\mathrm{q}}$ and $\mathrm{Y}=\mathrm{X}_{\mathrm{t}}^{(1)}-\mathrm{X}_{\mathrm{s}}^{(1)}$ over $\mathrm{T}^{*}$. Then

$$
\begin{gathered}
P\left\{\left\|X_{t}^{(1)}-X_{s}^{(1)}\right\| \geqslant \lambda\right\}=P\{M(Y) \geqslant \lambda\} \leqslant \\
\leqslant P\left\{(q-1) M^{\prime \prime}(Y)+\left|Y\left(l_{q-1}\right)\right| \geqslant \lambda\right\} \leqslant \\
\leqslant P\left\{(q-1) M^{\prime \prime}(Y) \geqslant \lambda r_{1}\right\}+P\left\{Y\left(l_{q-1}\right) \mid \geqslant \lambda r_{2}\right\} \\
r_{1}+r_{2}=1 .
\end{gathered}
$$

If $B^{\prime}$ is a block of $T^{*}, Y\left(B^{\prime}\right)=X\left((s, t) \times B^{\prime}\right)$, hence

$$
P\left\{\left|Y\left(B^{\prime}\right)\right| \geqslant \lambda\right\} \leqslant \lambda^{-\gamma}\left(m\left((s, t] \times B^{\prime}\right)\right)^{\beta}=: \quad \lambda^{-\gamma}\left(m^{*}\left(B^{\prime}\right)\right)^{\beta}
$$

So $Y \in C_{i}^{m^{*}}(\beta, \gamma)$, and by hm. (1.4)

$$
\begin{aligned}
P\left\{M^{\prime \prime}(Y)\right. & \left.\geqslant \lambda r_{1}(q-1)^{-1}\right\} \leqslant \lambda^{-2 \gamma_{K_{q}}(\gamma, \beta) x_{1}^{-2 \gamma}\left(m m_{1}(s, t]\right)^{2 \beta} \leqslant} \\
& \leqslant \lambda^{-2 \gamma_{K_{q}}(m(T))^{\beta} x_{1}^{-2 \gamma}\left(m_{1}(s, t]\right)^{\beta} .}
\end{aligned}
$$

Now if $B=(s, t] \times T^{*}$

$$
Y\left(1_{q-1}\right)=X\left(t^{\prime}, 1_{q-1}\right)-X\left(s, 1_{q-1}\right)=X(B)
$$

This implies

$$
\left.P\left\{\mid Y\left(l_{q-1}\right)\right\} \geqslant \lambda r_{2}\right\} \leqslant \lambda^{-\gamma} r_{2}^{-\gamma}\left(m_{1}(s, t]\right)^{\beta}
$$

Putting together our inequalities we get finally:

$$
P\left\{\left\|X_{t}^{(1)}-X_{s}^{(1)}\right\| \geqslant \lambda\right\} \leqslant\left(r_{1}^{-2 \gamma}(m\langle T\rangle)^{\beta} K_{q}+r_{2}^{-\gamma}\right)\left(\lambda^{-2 \gamma} \lambda^{-\gamma}\right)\left(m_{1}(s, t]\right)^{\beta}
$$

By the theorem in dimension 1:
$P\left\{M_{1}^{\prime \prime}(X) \geqslant \lambda\right\} \leqslant\left(r_{1_{o}}^{-2 \gamma}(m(T))^{\beta} K_{q}+r_{2_{o}}\right)\left(\lambda^{-2 \gamma_{v}} \lambda^{-4 \gamma}\right)(m(T))^{2 \beta}\left(1-\frac{J_{1}\left(T_{1}\right)}{m_{1}\left(T_{1}\right)}\right)^{\beta}$
where $r_{1_{0}}$ is the solution of the equation $2 K_{q}(m(T))^{\beta}\left(1-r_{1}\right)^{\gamma+1}=$ $=r_{1}^{2 \gamma+1}$ over $(0,1)$ and $r_{2_{0}}=1-r_{1_{0}} \square$

Remark. In step 3 we have in fact used a slight modification of the result of step 2 , to cover the $\left(\lambda^{-2} v \lambda^{-\gamma}\right)$ situation. As a referee has pointed out, this proof works only in case $\beta>1$. As we need this theorem with $\beta=1$ later on, we remark that an independent easy proof may be given for $\beta>1 / 2$ using induction on $q$ and Billingsley (3), Thm 12.6.
3. Convergence of processes indexed by $[0,1$ ? .

Theorem (3.1): Let $\left\{X_{n}\right\}_{n=1}^{\infty}$ be processes over $T=\{0,1\}^{q}$ vanishing on $\partial_{i n f} T$. Suppose that $X_{n} \in C_{i}^{m}(\beta, \gamma)$ for some $\beta>1 / 2, n=1,2, \ldots$.

Then:
(3.1.1) $\quad \lim \delta \downarrow o \underset{n \longrightarrow \infty}{\lim \sup } P\left\{w_{X_{n}^{\prime \prime}}(\delta) \geqslant \epsilon\right\}=0$
for all $\epsilon>0$ :

Proof: It is enough to show that

$$
\lim _{\delta \nmid 0} \quad \lim \sup _{\mathrm{n} \longrightarrow \infty} P\left\{w_{X_{n}^{\prime \prime}}^{(p)}(\delta) \geqslant \epsilon\right\}=0
$$

for all $p, l \leqslant p \leqslant q$, and $\in>0$.

Let
$(3.1 .2) w.(0, r ; n)=\operatorname{su},\left\{\min \left(\left\|\left(X_{n}\right)_{t}^{(p)}-\left(X_{n}\right)_{s}^{(p)}\right\|!\left\|\left(X_{n}\right)_{u}^{(p)}-\left(X_{n}\right)_{t}^{(p)}\right\|\right)\right\}$ $a \leqslant s \leqslant t \leqslant u \leqslant \tau$

Now, an application of theorem (2.1) to the process $Y_{n}$, defined over $T^{*}=[0,1]^{p^{-1}} \times[\sigma, \tau] \times[0,1]^{q-p}$ in such a way that for $\sigma \leqslant t \leqslant \tau$

$$
\left(Y_{n}\right)_{t}^{(p)}=\left(X_{n}\right)_{t}^{(p)}-(X)_{\sigma}^{(p)}
$$

(observe that $Y_{n}$ vanishes over $\partial_{\text {inf }} T^{*}$, has the same indrements that $X_{n}$ over $T^{*}$ 's blocks and that, as a consequence, it verifies condition $C_{i}^{\text {mi* }}(\beta, \gamma)$ over $T^{*}$, where

$$
\left.m^{*}(.)=m(.)-m\left(. \cap \partial_{\inf } T^{*}\right)\right)
$$

gives us
(3.1.3) $\mathrm{P}\{\mathrm{w}(\sigma, \tau ; n) \geqslant \epsilon\} \leqslant K \epsilon^{-4 \gamma}\left(m_{p}(\sigma, \tau]\right)^{2 \beta}\left(1-\frac{J_{p}(\sigma, \tau 1}{m_{p}(\sigma, \tau]}\right)^{\beta}$
for all $\epsilon, 0<\epsilon \leqslant 1$.

If $\delta=1 / 2 \mathrm{u}$ then
(3.1.4)

$$
\left\{w_{x_{n}}^{\prime \prime(p)}(\delta) \geqslant e\right\} \subset A_{1} \cup A_{2}
$$

where

$$
\begin{aligned}
& A_{1}=\bigcup_{i=0}^{u-1}\{w(2 i \delta,(2 i+2) \delta ; n) \geqslant \epsilon\} \quad \text { and } \\
& A_{2}=\bigcup_{i=0}^{u-2}\{w((2 i+1) \delta ;(2 i+3) \delta ; n) \geqslant \varepsilon\}
\end{aligned}
$$

From (3.1.3) and (3.1.4) we get
(3.1.5)

$$
P\left\{w_{x_{n}}^{\# \#}(p)(\delta) \geqslant \varepsilon\right\} \leqslant K \epsilon^{-4 \gamma} \quad\left(I_{1}+I_{2}\right)
$$

where

$$
I_{1}=\sum_{i=0}^{u-1}\left(m_{p}(2 i \delta,(2 i+2) \delta]\right)^{2 \beta}\left(1-\frac{J_{p}(2 i \delta,(2 i+2) \delta 1}{m_{p}\left(2 i \delta_{r}(2 i+2) \delta I\right.}\right)^{\beta}
$$

and

$$
I_{2}=\sum_{i=0}^{u-2}\left(m_{p}((2 i+1) \delta,(2 i+3) \delta]\right)^{2 \beta}\left\{1-\frac{J_{p}((2 i+1) \delta,(2 i+3) \delta I}{m_{p}((2 i+1) \delta,(2 i+3) \delta I}\right\}^{\beta}
$$

Remark: The previous theorems also hold if condition $X \in C_{i}^{\text {m }}(\beta, \gamma)$ is replaced by: $X$ defined over ( $U_{1} \times U_{2}, P_{1} \times P_{2}$ ) and for all $u_{1} \in U, X_{t}\left(u_{1}, \ldots\right) \in c_{i}^{m}(\beta, \gamma)$. We then say that $x \in \tilde{C}_{i}^{m}(\beta, \gamma)$.

Theorem (3.2): A sequence, $\left\{P_{n}\right\}_{n=1}^{\infty}$, of probability measures over $\left(D_{q}, D_{q}\right)$ is tight if:
i) For all $\eta>0$, there exists $a \in R$ such that:

$$
p_{n}\left\{x: \sup _{t}|x(t)|>a\right\} \leqslant \eta, n=1,2 \ldots
$$

ii) For all positive $\epsilon, \eta$, there exist $\delta, 0<\delta<1$, and $n_{0}$, such that for ali $n \geqslant n_{0}$ :
a)

$$
P_{n}\left\{x: w_{x}^{\prime \prime}(\delta) \geqslant \epsilon\right\} \leqslant \eta
$$

b) $\quad P_{n}\left\{x: w_{x}^{(p)}[0, \delta) \geqslant \epsilon\right.$, for some $\left.p, 1 \leqslant p \leqslant q\right\} \leqslant \eta$.
c) $\quad p_{n}\left\{x: w_{x}^{(p)}[1-\delta, 1) \geqslant \epsilon\right.$, for some $\left.p, 1 \leqslant p \leqslant q\right\} \leqslant \eta$.

> Proof: We show that a), b) and c) imply
ii) of tho. (1.6). The argument of Billingsley (2), the.
(14.4), applied to the functions $t \longrightarrow\left\|x_{t}^{(p)}\right\|$, lead to
(3.2.1) $\quad P_{n}\left\{x: w_{x}^{(p)}(\delta / 2)>\epsilon / q\right\} \leqslant P_{n}\left\{x:{ }_{x}^{(p)}[0, \delta) \geqslant \epsilon / 6 q\right\}+$
$+P_{n}\left\{x: w_{x}^{(p)}[1-\delta, 1) \geqslant \epsilon / 6 q\right\}+P_{n}\left\{x: w_{x}^{\prime \prime}(p)(\delta) \geqslant \epsilon / 6 q\right\}$

Now our theorem follows from $w_{x}^{\prime}(\delta) \leqslant \sum_{p=1}^{q}{\underset{x}{w}}_{(p)}^{(\delta) .}$

As an application of the previous results we get the folowing theorem, which generalizes theorem (2.3) of Gink \& Marcur (4), to processes indexed by $[0,1]^{\circ}$.

Theorem (3.3): Let $\left\{X_{n}\right\}_{n=1}^{\infty}$, $X$, be $D_{q}$-vanned random variables, vanishing on $\partial_{i n f} T$, and such that:
i) The finite dimensional distributions of the $X_{n}$ converge wealily to the corresponding distributions of $x$.
ii) $\mathrm{X}_{\mathrm{n}} \in \widetilde{\mathrm{C}}_{\mathrm{i}}^{\text {m }}(\beta, \gamma), \mathrm{n}=1,2, \ldots$, for some $\beta>1 / 2$, and $\gamma>0$.
(iii) For all $\epsilon>0$
$\lim \lim _{\delta \downarrow 0} \sup _{n \rightarrow \infty} P_{n}\left\{x: w_{x}^{(p)}\{1-\delta, 1)>\epsilon\right.$, for some $\left.p, 1 \leqslant p \leqslant q\right\}=0$

Then $\left\{P_{n}=L\left(X_{n}\right)\right\}_{n=1}^{\infty}$ converge weakly to $L(X)$, as a sequence of probability measures on ( $\mathrm{D}_{\mathrm{q}}, \mathrm{D}_{\mathrm{q}}$ ).

Proof: It is an induction on $q$. We verify conditions i) and ii) of the previous tho.

With respect to ii): a) is a consequence of hm. (3.1),
c) is the hypothesis iii). Let us see i).

$$
P\left\{\sup _{t \in T}|x(t)|>a\right\}=P\left\{\sup _{t \in[0,1]}\left\|x_{t}^{(p)}\right\|>a\right\}
$$

## Hence:

$$
\begin{aligned}
& P\left\{\sup _{t \in T}\left|\left(x_{n}\right)_{t}\right|>a\right\}=P\left\{\sup _{t \in[0,1]}\left\|\left(x_{n}\right)_{t}^{(1)}\right\|>a\right\} \leqslant \\
& \leqslant P\left\{w_{X_{n}^{\prime \prime}}^{(1)}(\delta)>1\right\}+P\left\{\max \quad \sup _{1 \leqslant i \leqslant k} \quad t^{*} \in T_{2} \times \ldots \times T_{q}\left|\left(X_{n}\right)_{t}^{(1)}\left(t^{*}\right)\right|>a_{0}\right\} \leqslant \\
& \left.\leqslant \operatorname{Pim}_{X_{n}^{\prime \prime}}^{(1)}(\delta)>1\right\}+\sum_{i=1}^{k} P\left\{\sup _{t^{*} \in T_{2} \times \ldots \times T_{q}}\left|\left(X_{n}\right)_{t_{i}}\right|>a_{o}\right\} .
\end{aligned}
$$

Now because of

$$
\begin{aligned}
& p\left\{w_{\left(x_{n}\right)_{t_{i}}^{(p)}}^{(1)}[1-\delta, 1)>\epsilon, \text { for some } p^{\prime}, 2 \leqslant p^{\prime} \leqslant q\right\} \leqslant \\
& \leqslant p\left\{w_{x_{n}}^{(p)}[1-\delta, 1)>\epsilon, \text { for some } p, 1 \leqslant p \leqslant q\right\}
\end{aligned}
$$

the processes $\left(X_{n}\right)_{i}^{(1)}$ satisfy $\left.i\right)$, ii) and iii) of our theorem, $i=1,2, \ldots, k$. By induction hypothesis there exists $\left\{a_{i}\right\}_{i=1}^{k} \quad$ such that

$$
p\left\{\sup _{t} *\left(x_{n}\right)_{t_{i}}^{(1)} \mid>a_{i}\right\} \leqslant \eta / 2 k
$$

Given $\eta>0$, let $\delta>0$ be such that

$$
\left.\mathrm{P}_{\mathrm{i}}^{\mathrm{w}_{\mathrm{n}}^{\prime \prime}}{ }^{(1)}(\delta)>1\right\} \leqslant \eta / 2
$$

choose $0=t_{0}<t_{i}<\ldots \quad t_{k}=1$ such that $t_{i}-t_{i-1}<\delta$ and $a_{0}=\max \quad a_{i}$. $i=1, \ldots k$

Then if $a=a_{0}+1$ :

$$
P\left\{\sup _{t \in T} I\left(X_{n}\right)_{t} I>a\right\} \leqslant \eta .
$$

This proves that i), ii) and iii) imply i) of the. (3.2), by induction on $q$.

It only rests to verify condition b) of ii).

By induction hypothesis $\left(X_{n}\right)_{\delta}^{(p)} \xrightarrow{w}(x)_{\delta}^{(p)}$. Hence, $\left\|\left(X_{n}\right)_{\delta}^{(p)}\right\| \xrightarrow{w}\left\|(x)_{\delta}^{(p)}\right\| \quad$ also. Now observe that

$$
\|(\mathrm{x})_{\delta}^{(\mathrm{p}) \| \frac{\mathrm{Pr}}{\delta \downarrow 0}} 0
$$

as a consequence of the right continuity of $(X)_{t}^{(p)}$ and $(x)_{o}^{(p)}=0$.

Given positive $\eta$ and $\epsilon$, let $\delta_{0}>0$ be such that if $\delta<\delta_{0}$

$$
P\left\{\left\|(X)_{\delta}^{(p)}\right\| \geqslant \epsilon\right\}<\pi / 2 .
$$

Then

$$
\underset{n \rightarrow \infty}{\operatorname{imsup}} P\left\{\left\|\left(X_{n}\right)^{(p)}\right\| \geqslant \epsilon\right\} \leqslant P\left\{\left\|(x)_{\delta}^{(p)}\right\| \geqslant \epsilon\right\} \leqslant \pi / 2 .
$$

$$
\left\{x: w_{x}^{(p)}[0, \delta) \geqslant 4 \epsilon\right\} \subset\left\{x: w_{x}^{\prime \prime}(p)(\delta) \geqslant \epsilon\right\} \cup\left\{x:\left\|x_{\delta}^{(p)}-x_{0}^{(p)}\right\| \geqslant \epsilon\right\}
$$

we get:

$$
\underset{n}{\lim \sup _{\infty}} P_{n}\left\{x: W_{x}^{(p)}[0, \delta) \geqslant 4 \epsilon\right\} \leqslant \eta .
$$

This proves b) and the theorem.

In applications quite frequently we don't know that $X \in D_{q}$. It is then useful to have the following variant of the previous thm.., whose proof requires the same argument as above.

Theorem (3.4): Let $\left\{X_{n}\right\}_{n=1}^{\infty}$ be as in thm. (3.3). Suppose:
i) The finite dimensional distributions of $X_{n}$ are weakly convergent and

$$
\lim \lim _{\delta \neq 0} \sup _{n} P_{n}\left(x:\left\|x_{\delta}^{(p)}\right\| \geq \epsilon\right\}=0
$$

for all $\epsilon>0$ and all $p, I \leqslant p \leqslant q$.
ii) $X_{n} \in C_{i}^{m}(\beta, \gamma), n=1,2, \ldots$, for some $\beta>1 / 2$ and $\boldsymbol{\gamma}>0$.
iii) $\lim \lim _{\delta \downarrow 0} \sup _{n \rightarrow \infty} p_{n}\left\{x: w_{x}^{(p)}[1-\delta, 1)>\epsilon\right.$, for score $\left.p, l \leqslant p \leqslant q\right\}=0$ for all $\epsilon>0$.

Then $\left\{P_{n}=L\left(X_{n}\right)\right\}_{n=1}^{\infty}$ is weakly convergent $\square$
4. Regularity of processes with independent increments. Theorem (4.1): If $x \in C_{i}^{\text {II }}(\beta, \gamma)$, where $\beta>1 / 2, \gamma>0$, then $X$ has a version with sample paths in $D[0,1]^{q}$.

Proof: Let $\delta_{o}<1 / 2$. For $t \in[0,1]^{q}$ define:

$$
\begin{aligned}
f_{\delta_{0}}^{i}(t)= & \left(t_{1}, \ldots, t_{i-1}, t_{i} I_{\left[\delta_{0}, 1-\delta_{0}\right]}\left(t_{i}\right)+\delta_{0} I_{\left[0, \delta_{0}\right]}\left(t_{i}\right)+\right. \\
& \left.\left(1-\delta_{0}\right) I_{\left(1-\delta_{0}, 1\right]}\left(t_{i}\right), t_{i+1}, \ldots, t_{q}\right)
\end{aligned}
$$

for all $i, \quad l \leqslant i \leqslant q$.

$$
\begin{gathered}
\bar{f}_{\delta_{0}}(t)=\left(\left(1-2 \delta_{o}\right)^{-1}\left(t_{1}-\delta_{o}\right), \ldots,\left(1-2 \delta_{0}\right)^{-1}\left(t_{i}-\delta_{o}\right), \ldots,\left(1-2 \delta_{o}\right)^{-1}\left(t_{q}-\delta_{o}\right)\right) \\
f_{\delta_{0}}(t)=\left(\bar{f}_{\delta_{0}} \circ f_{\delta_{0}}^{1} \circ f_{\delta_{0}}^{2} \ldots \ldots \circ f_{\delta_{0}}^{q}\right)(t) .
\end{gathered}
$$

We first prove that the process $Y_{t}=X_{f_{\delta}}(t)$ on $[0,1]^{q}$, has a version with sample paths in $D[0 ; 1]^{q}$.

Observe that $y \in \widetilde{C_{i}^{m}}(\beta, \gamma)$, if

$$
\tilde{m}(.)=m\left(\vec{f}_{\delta_{0}}\left(. \cap\left[\delta_{0}, 1-\delta_{0}\right] G_{j}\right)\right.
$$

For each $n$ we define a process $X_{n}$ on $[0,1]^{q}$, constent over each rectangle of the dyadic net of order $n$, and equal to the value of $Y$ at "south-west" vertex, ie.:

$$
y_{n}(t)=Y\left(\left(i_{1}-1\right) 2^{-n} \ldots \ldots\left(i_{q}-1\right) 2^{-n}\right)
$$

for all $t \in\left[\left(i_{2}-1\right) 2^{-n}, i_{1} 2^{-n}\right) \times \ldots x\left[\left(i_{q}-1\right) 2^{-n}, i_{q} 2^{-n}\right)$, where $1 \leqslant i_{1} \leqslant 2^{n}, \ldots, 1 \leqslant i_{q} \leqslant 2^{n}$.

We show that $\left\{Y_{n}\right\}_{n=1}^{\infty}$ is a tight sequence. First, an argument like that in the proof of tho. (3.1) shows that.
(4.1.1) $\quad \lim _{\delta \downarrow 0} \quad \lim _{n \rightarrow \infty} \sup _{\infty} \quad P\left\{w_{Y_{n}}^{\prime \prime}(\delta) \geqslant \epsilon\right\}=0$
for all $:>0$.

In fact: If $Z_{n}$ is defined over $T^{*}=[0,1]^{p-1} \times[\sigma, r] \times$ $x[0,1]^{q-p}$ from $y_{n}$, as in the (3.1) $y_{n}$ is defined from $X_{n^{\prime}} Z_{n}^{m(2)}$ represents the restriction of $Z_{n}$ to the diadic net, $\mathrm{T}_{\mathrm{m}(2)}^{*}$, of $\mathrm{T}^{*}$, and $v^{(\mathrm{m})}$ is defined over $\mathrm{T}_{\mathrm{m}(2)}^{*}$ like the 0 of step 2, in the proof of the. (2.1), then:

$$
\begin{aligned}
& P\left\{M_{p}^{\prime \prime}\left(Z_{n}\right) \geqslant \lambda\right\}=\lim _{m \rightarrow} P_{i}\left\{M_{p}^{\prime \prime}\left(Z_{n}^{m(2)}\right) \geqslant \lambda\right\} \leqslant \\
& \leqslant \lim _{\mathrm{m} \rightarrow \infty} \mathrm{~K} \lambda^{-4 \gamma}\left(v_{\mathrm{p}}^{\mathrm{m}}(\sigma, \tau]\right)^{2 \beta}\left(1-\frac{\mathrm{J}_{v_{\mathrm{p}}}(\sigma, \tau)}{v_{\mathrm{p}}^{\mathrm{m}}(\sigma, \tau)}\right)^{\beta}= \\
& =K \lambda^{-4 \gamma}{\underset{m}{p}}_{2 \beta}^{(\sigma, \tau]}\left(1-\frac{J_{p}(0, \tau]}{\widetilde{m}_{p}(0, \tau]}\right)^{\beta} .
\end{aligned}
$$

Hence, $\left\{Y_{n}\right\}$ satisfies (3.1.3), and now all follows as in the. (3.1)'s proof.

If $2^{-k}<\delta$ and $T_{k(2)}$ denote the set of points of the $2^{-k}$-dyadic net in $T=[0,1]^{q}$, then

$$
\sup _{t \in T}\left|Y_{n}(t)\right| \leqslant \max _{t \in T_{k(2)}}\left|y_{n}(t)\right|+q w_{Y_{n}^{\prime \prime}}(\delta) .
$$

Moreover, observe that the variables

$$
\max _{t \in T_{k(2)}} Y_{n}(t)!, \quad n=k, k+1, \ldots
$$

are identically distributed. This, together with (4.l.1) gives condition i) of our tho. (3.2). Besides, $\left\{Y_{n}\right\}_{n=1}^{\infty}$ satisfies b) and c) of ii), the. (3.2), by construction.

Hence, $\left\{Y_{n}\right\}_{n=1}^{\infty}$ is tight. If $W$ is the weak limit of some subsequence, then it is easy to see that $W$ is a version of $Y$, looking first at dyadic points, and approaching then any point by dyadics.

The application $\overline{\mathrm{f}}_{\delta}$ being bijective and continuous between $\left[\delta_{0}, 1-\delta_{o} l^{q} \text { and }[0,1]^{q} \text {, and } X_{t}=Y_{\left(\bar{f}_{0}\right.}\right)^{-1}(t)$, the theorem is proved.

Remarks and comments.
a) It will be very interesting to get a result like tha. (2.1) for processes whose increments are not necessarily independent. I don't know at present how to do this.
b) All previous results extend easily to $(0, \infty)^{q}$-indexed processes using well known results on $\mathrm{D}[0, \infty)^{\mathrm{q}}$ (see B.G. Ivanoff (5) ).
c) Using above results and some others, (which constitute my Doctoral Thesis, as presented at the Universitat Autonoma de Barcelona, Spain), we can prove the Central Limit Theorem for processes that admit a representation as stochastic integrals w.r.t. Levy processes with multidimensional time parameter. This will appear elsewhere.
d) Finally I want to express my indebtness and gratitude to Professor E. Gine, that suggested this problems to me and has given efficient help, whenever needed.
